I chose to model a LOOK pivot binding, because I love skiing and the design of bindings specifically has always interested me. I also wanted a challenging assembly, and I knew the pivot bindings have many complex parts. My strategy was to section it out, so first I started with the toe-piece as it had less parts, and then I moved on to the heel-piece which was much more complicated. Everything went pretty smoothly, until the end when I started doing my animations. My heel piece movement had some weird bugs and would sometimes be undefined and other times be fully defined. It's still sometimes a little strange but rebuilding seems to define it.

I didn't use any references other than my own old pair of bindings. I don't think I would have been able to model the complexity of the parts just through pictures or videos, so I'm glad I was able to take mine apart. Once I got the toe piece and heel piece apart, It was pretty easy to see each component and how they fit together, which really helped modelling. I was also able to actually measure distances and details myself which made it a lot easier as well.
